Worksheet: JPEG Compression Artifact

Application Program Required

Adobe Photoshop 5.5 or later

Objectives

1. To take a closer look at the JPEG artifact.
2. To learn where JPEG artifact is most visible.

Introduction

JPEG is a common file format for Web images. Many digital cameras also save digital photographs directly in JPEG format, which, for some cameras, may be the only choice of the file format.

Have you noticed any ugly artifact in some JPEG images? If you are posting your portfolio of art work as JPEG images on the Web, you should understand how the JPEG compression affects your image quality and how to minimize the artifact.

The example image you will use in this exercise has many solid color areas and edges where sharp color changes occur. It is not the type of images that JPEG compression is best for because the JPEG compression artifact is more pronounce. However, this will make it easy for you to see the artifact in this exercise.

Instructions

A sample image, called `solid-color-ex.tif`, can be downloaded from the companion Web site of the book. Look under JPEG Compression Artifact. This example image is a TIF file with no image compression. The image is made up of large areas of solid colors and gradients.

I. Compression Quality and File Size

1. Open the image with Adobe Photoshop, and convert this image into JPEG files with different compression level.
2. If you have access to Photoshop 5.5 up to CS2, choose **File > Save for Web...**
If you have Photoshop CS3 or later, choose **File > Save for Web & Devices...**
3. Click the 4-Up tab (Figure 4 and Figure 5, on the last page of this worksheet), so you can see the original TIF image and three optimized images of different JPEG compression settings simultaneously.
4. Click on each of these three different optimized images, and select JPEG from the Optimized File Format dropdown menu. Then select from the Compression Quality dropdown Low, Medium, and Maximum.

1. Note down in the table the file sizes and the time to transfer the file over a specific network connection speed:

Compression Quality	File Size (KB)	Transfer Time (sec.) at what Network Connection Speed
Original TIF		-----
Low	smallest	should be the shortest
Medium		
Maximum	largest	should be the longest

2. Which compression quality among the three in the table above gives the best image quality?
Maximum
3. Which compression quality among the three in the table above gives the worst image quality?
Low

- Zoom in the images to look closely and compare the original TIF image with the three optimized images. Do you see the difference?

- Where are the artifacts *most* visible? **A**
A. At the intersection of very different colors
B. Within a solid color away from the edge of the color

- Select the optimized image that has the **Compression Quality** set to **Maximum**; you can also directly set the **Quality** to 100. Save the optimized image as `max . jpg`.

II. Take a Closer Look at the JPEG Image

Open this `max . jpg` file in Photoshop. It may look the same as the original TIF image to the naked eyes. However, some colors are altered, especially the pixels around the edges where sharp changes of colors occur. Try these:

- Use the **Magic Wand** selection tool, with its **Tolerance** set to zero, click to select a solid color area in the original TIF image. The circumference of the selection should follow nicely around the outline of that solid color area (Figure 1a).
- Now, try the same on the `max.jpg`. How is the shape of the selection? Most of the middle area is in the selection but the edge around the solid color is not. And, the selection outline is a little jagged (Figure 1b).

(a)
Figure 1

(b)

- Why can you tell from the observation in the above steps that the `max . jpg` is not exactly the same as the original TIF? (First, what does setting the **Tolerance** of **Magic Wand** to zero means?)
The Tolerance of the Magic Wand tool being zero enforces that it only selects one single color.
The above steps demonstrate that the originally solid color area is not anymore a single solid color in the max.jpg. Otherwise the whole solid color area would have been selected with the Magic Wand tool at Tolerance set to zero.

Lower compression quality settings can impose very visible alternations on the image, but the **Maximum** setting causes only indiscernible alterations. The **Maximum** setting gives larger file size but it is still much smaller than the original TIF.

But how would this affect the way you create your digital images? This affects how you use the image. For example, any images that are intended for further editing should not be kept in JPEG format because every time you save a JPEG file, it gets altered even if you have not changed anything. (See the following sections)

III. Resaving a JPEG Even at 100% Will Alter the Image

1. Open `max . jpg` in Photoshop and save it as `max2 . jpg`. You can choose the **Maximum** compression quality.
2. Close the file and open the `max2 . jpg` in Photoshop.

Since the compression quality is set to **Maximum**, the alternation caused by the JPEG artifact is indiscernible. To see if `max2 . jpg` is really altered from `max . jpg`, try the following:

- i. Use the **Magic Wand** selection tool, again with its **Tolerance** set to zero, click to select a solid color area in the `max . jpg`. Fill the selection with a distinctive color, such as black. (**Edit > Fill...**)
- ii. Now, try the same on the `max2 . jpg`.
- iii. Zoom in both `max . jpg` and `max2 . jpg`. Compare the newly filled color shapes. They are different!

IV. Resaving a JPEG Will Lower the Quality

Open the original TIF file in Photoshop and save it as JPEG at the compression quality set to zero. Name the new file as `max0 . jpg`.

Open this `max0 . jpg` in Photoshop. Zoom in the image to 600%. You will see that the colors seem to be grouped in square blocks (Figure 2).

Figure 2

6. Do all the square blocks have the same pixel dimension?
Yes
7. What is the pixel dimension of the square blocks?
(There are many ways to find out the pixel dimension of the square blocks. One way is to use a Rectangular Marquee Tool to make a selection around a square block. Then, look at the Info palette for the width and height of the selection.)
8 pixels × 8 pixels

Why are the colors grouped in square blocks of such a pixel dimension? It is related to the JPEG compression algorithm—how it compresses the image file. For the sake of making the artifact more visible, we have you save a JPEG at zero compression quality. You may also see such artifact in other JPEG files, especially those are saved at low compression quality or have been saved as JPEG over and over. If you are interested in learning more about the JPEG compression algorithm, an in-depth discussion can be found in the digital imaging chapter of the Computer Science Module.

V. Resaving a JPEG at 100% Will NOT Recover the Quality

With this `max0.jpg` still open in Photoshop, save it as `max0max.jpg` by setting the **Compression Quality** to **Maximum**. Open `max0max.jpg` in Photoshop and note its image quality.

8. The image quality of `max0max.jpg` is: **B**
- A. recovered, and is as good as, or almost as good as, the `max.jpg` – the JPEG saved directly from the original TIF at the maximum compression quality.
 - B. worse than `max0.jpg`, or at least there is not any observable improvement over `max0.jpg`.

VI. Summary and Conclusions

9. **True/False:** Saving an image as JPEG at lower compression quality for Web images can reduce the image's network transfer time. **T**
10. **True/False:** One should keep the original image for further image editing. **T**
11. **True/False:** The quality of an image file that is saved as JPEG over and over at the maximum compression quality is as good as saving the file as PSD (Photoshop file). **F**

for examples, TIF, PNG, BMP
17. The most visible JPEG artifact occurs at the edges where sharp color changes occur

Worksheet: JPEG vs. GIF vs. PNG

Application Program Required

Adobe Photoshop 5.5 or later

Objectives:

1. To learn to optimize files in JPEG, GIF and PNG format and adjust the compression settings to achieve the balance between the file size and overall image quality.
2. To learn the type of images that each of these file formats is most effective at compressing.

Introduction:

The three image file formats supported by the Web browsers are JPEG, GIF and PNG. Each employs different compression algorithms to make the file size smaller. Because of the different algorithms, they work best with different types of images.

The JPEG format works best with continuous-tone images with a broad color range and subtle color and brightness variations, such as photographs and images with gradients. It supports 24-bit color (millions of colors). JPEG compression is a lossy compression which means that during compression, image data is lost to make the file size smaller. High JPEG compression tends to blur the image detail. (See the JPEG worksheet for more detailed hands-on experimentation.)

The GIF format supports up to 8-bit color (256 colors), but it also supports background transparency. It is most effective for images with solid colors such as illustrations, logos, and line art. It uses a palette of up to 256 colors to represent the image. If the original image has more than 256 colors, then you will need to reduce the colors. There are several color reduction options available, or you can also customize the colors to be included in the palette. A sequence of images can also be put together into an animated GIF.

The PNG-8 format uses up to 256 colors to represent the image; similar to GIF. The PNG-24 supports 24-bit color, including transparency information. Unlike the JPEG format, PNG is a non-lossy compression method. Depending on the image and the JPEG compression, PNG-24 may yield a larger file size than JPEG compressed from the same image.

Instructions:

Several sample images can be downloaded from the book's Web site. Look under Chapter 3's worksheet on JPEG vs. GIF vs. PNG.

1. Download the sample images from the book's Web site, or use images of your own. (Get instructions from your instructors about the number and type of images you need to use to complete this exercise.) Each image in this worksheet is provided with a brief description on the characteristics of the image. If you are using your own images, write a brief description about the unique characteristics of the image and how you obtained the image (e.g. captured directly from a digital camera as what file format, scanned from a slide, a negative, or a print, at what color depth and in what file format.)
2. Open the image in Adobe Photoshop. To optimize the image for the Web, choose File > Save for Web ...
3. Click on the 4-Up tab to see the original image and three possible optimized images. (See the figure of the screen capture of the Save for Web ... dialog box below. The screen capture shows the JPEG compression options on the right. Compression options vary with file format. Also read the Help to find out more about how to use the Save for Web dialog box.)
4. For each image, try each of the following file types: JPEG, GIF, PNG-8, and PNG-24. Determine the best compression settings for each of these file formats for the same image. Note down the settings and the file size on the following pages. Circle the one that you think it gives the best balance between file size and image quality. And, comment on the resulting optimized image and give the rationale for your decision.

Figure 1. Save for Web ... dialog box in Adobe Photoshop CC2014.

Description and characteristics of the image

This is a slide of a pen-and-ink drawing, scanned at 24-bit color. The background had a cast of non-uniform gray when it was first scanned. This image has been cleaned up to show a uniform white background. Compare the GIF file with the one before the cleanup. See why it is worthwhile to spend a little more effort to clean up the scanned images, especially art drawings, before editing and optimizing.

This is also a continuous tone image because it was scanned from a slide. But you can use a file compression method below to make it look crisp like the original art work. Which file format is the best choice for this image?

For each of the file formats below, **fill in the optimized settings and file size**, especially those highlighted in yellow. Then, **circle** the file format that you think is the best for this image for the Web.

Answers to Worksheet: Making Sense Out of Megapixels

Objectives:

1. To learn what megapixels mean with regard to digital cameras.
2. To learn to correlate the number of megapixels to the print size.

Introduction:

Many digital cameras are advertised with the number of megapixels. Generally, within the same time period, the higher the number of megapixels, the more expensive the cameras are. But what is the practical meaning of the number of megapixels besides just being an indicator of the cost? If you are going to pay more for more megapixels, you should know why and how it affects the image quality of your creative photography work.

Instructions:

1. Go on the web and look up the specification of your choice of a point-and-shoot digital camera model or the digital camera of a cell phone. Note the maximum number of megapixels. Also note the maximum pixel dimensions of the image (width and height).

Fill in the information of the camera you choose:

Brand:

Model:

Price (approx.):

The number of effective pixels (in megapixels):

The maximum pixel dimensions of the image:

Width:

Height:

2. Calculate the total number of pixels of an image by multiplying the maximum pixel width by the maximum pixel height. Convert this number into megapixels.

Note: 1,000,000 pixels = 1 megapixel

Show your calculation here.

Compare your number with the reported effective megapixels of the camera. Does it match?

(This should match.)

3. If you are going to print the image on an inkjet printer at 300 ppi (pixels per inch), what will the print size of the image shot with this digital camera of your choice be?

Show your calculation here.

What will the print size be if you print the image at 150 ppi?

4. Using the camera of your choice in Question 1, what is the printing ppi setting for an 11-by-17-inch (a two-page spread in a magazine) printout?

Show your calculation.

5. The number of megapixels of newer models of digital cameras is getting higher and higher. To help you quickly correlate this number with the approximate print size, let's calculate the approximate print size per megapixel.

Before doing the calculation, you need to understand that the relationship between print size and megapixel is more complicated than you may have expected. It is because megapixel represents an "area"—it is a *product* of the width (in pixels) by the height (in pixels). If you want to know the print size in width-by-height, you need to know the pixel dimension of both the width and the height. Just the number of megapixel does not give you this information. It is because the same area size can be made up with many possible combination of width and height. Say, for 1 megapixel, it can be 1000 x 1000 pixels, 500 x 2000 pixels, or approximately 1155 x 866 pixels, ...etc. Therefore, to correlate the print size to megapixels, you should think in area (square inches) first.

Say, for a 1000-by-1000-pixel image (1 megapixel), what is the approx. print size (in square inches) if the image is printed at 300 ppi? Show your calculation.

1000 pixels / 300 ppi = 3.33 inches
print size in square inches = 3.33 inches x 3.33 inches = 11.1 inches²

What is the approx. print size (again, in square inches) per megapixel if the image is printed at 150 ppi? Show your calculation.

1000 pixels / 150 ppi = 6.67 inches
print size in square inches = 6.67 inches x 6.67 inches = 44.5 inches²

6. Say that you want to print your digital photography work at 300 ppi in 11 x 17 inches. What should be the megapixels of the camera you are looking for?

Show your calculation.

11 inches x 300 ppi = 3300 pixels

17 inches x 300 ppi = 5100 pixels

3300 pixels x 5100 pixels = 16,830,000 pixels $\cong$ 17 megapixels

7. The camera with such a large number of megapixels may be too expensive for most people. However, you can lower the printing resolution. Generally, printing at **240 ppi** on an inkjet printer can give a good quality.

What is the minimal megapixels requirement? Show your calculation.

11 inches x 240 ppi = 2640 pixels

17 inches x 240 ppi = 4080 pixels

2640 pixels x 4080 pixels = 10,771,200 pixels $\cong$ 11 megapixels

If your choice of camera does not have high enough resolution to give an 11-by-17-inch printout at 240 ppi, suggest a camera that has this resolution:

Worksheet: Photoshop Basics – Using Layers

Application Program Required

Any of Adobe Photoshop CC2014

Objective

To review layers.

Instructions

Fill out the worksheet. Refer to the section *Using Layers* in the Photoshop Help.

Circle or mark the answers on the Layers panel on the left if needed.

About the *Background* layer:

- **True/False:** An image can have only one *Background*. **T**
- **True/False:** You can change the stacking order of a *Background*, its blending mode, or its opacity, like the regular layer. **F**
- **True/False:** When you create a new file with transparent content, the image does not have a background layer. **T**
- How do you convert the *Background* layer to a regular layer?
double-clicking on the Background layer

To create a new layer: for example: click the "Create a new layer" icon, or click on the panel menu icon at the upper right of the Layers panel and select "New Layer..."

To delete a layer: for example: select the layer and click the "Delete layer" icon, or click on the panel menu icon in the Layers panel and select "Delete Layer"

To duplicate a layer: For example: Drag the layer to the "Create a new layer" icon, or click on the panel menu icon in the Layers panel and select "Duplicate Layer..."

To select a layer: Do one of the following:

- Click a layer in the Layers palette.
- Select the **Move** tool, **right-click** in the image, and choose a layer from the context menu. The context menu lists all the layers that contain pixels under the current pointer location.
- Select the **Move** tool, **Ctrl-click** in the image. The topmost layer/group under the cursor will be selected.
- Select the **Move** tool and check **Auto-select** option in the **Move** tool options (in the Option bar), the topmost layer containing pixels under the cursor will be selected whenever you click on the image.

To toggle the visibility of a layer: Click on the eye icon next to the layer

To rename a layer: Double-click on the layer name in the Layers panel

To set opacity of a layer: Change the Opacity value at the upper right of the Layers panel

To set the blending mode of a layer: Use the Blending mode dropdown at the upper left of the Layers panel

To apply layer styles such as drop shadow and bevel to a layer: Double-click on the layer thumbnail in the Layers panel to open Layer Style window, and then select the style

Stacking order of layers:

To rearrange the order of layers: Drag the layers in the Layers panel

How does the stacking order of the layers affect the image? The content in the layer on top blocks the content of the layers below it.

Layer groups:

To organize/group layer together: For examples: (1) Click the "Create a new group" icon in the Layers panel and drag the layers in the empty group, or (2) shift-select the layers, and click on the panel menu icon in the Layers panel and select "New Group from Layers..."

What are the advantages of grouping layers? For examples, you can toggle the visibility of multiple layers as a group, assign blending mode as a group, and reposition their content as a group.

Linking layers:

To link multiple layers: Select the layers, and click on the panel menu icon in the Layers panel and select "Link Layers..."

What is the advantage of linking multiple layers? For example, it lets you reposition the content of the linked layers together.

Layer masks:

To create a layer mask: Layer > Layer Mask

What do layer masks do? To hide portions of the layer and reveal the layers below

Clipping masks:

To create a clipping mask: Place the masking layer below the maskee layer. Hold down Alt (Windows) or Option (Mac OS) and click on the line between these two layers.

What do clipping groups do? They let you use the content of a layer to mask the layers above it.

Adjustment layers:

To create an adjustment layer: Layer > New Adjustment Layer

What do adjustment layers do? To apply image adjustment without permanently altering the pixel of the image.

Locking a layer:

What do locking a layer for? To prevent certain properties of a layer from being altered.

What properties of a layer can be locked? transparent pixels, image pixels, position

To lock a layer: Click on one or more of the four Lock icons on top of the Layers panel.

To move the content of multiple layers simultaneously: You can link the layers first, or create a layer group for them.

How does the number of layers affect the image file size? What would you do to minimize the file size of the final image for printing?

More layers makes the file size larger. It will take longer time to print. To reduce the time required to process the file during printing, flatten the image before printing.
